**Supplementary Figure 1. Graphic alignment highlighting the structural similarities between Rhopr-IR and human IR.** The IR monomers were aligned, and subunits A and B are highlighted by green and purple boxes, respectively. Signal peptides are highlighted in bright pink, followed by Leu-rich domains highlighted in pale pink and Cys-rich domains in light grey. Disulfide bonds are identified by yellow boxes over Cys residues, connected by yellow lines when the bonds are formed within the monomer. Fibronectin Type-III domains are

indicated by purple and grey boxes. The Cys residues that form disulfide bonds involved in the dimerization of the receptor are indicated by yellow/dark blue boxes over said residues. The Cys residues that form the disulfide bonds between subunits A and B of each monomer, are indicated by yellow/dark blue boxes over the residues and connected by yellow lines. The transmembrane regions are highlighted by red boxes, and the Tyr kinase catalytic domain by dark green boxes. Tyr residues that are phosphorylated upon activation of the receptor are indicated with small orange boxes. ATP-binding sites between the active site and the receptor signature are indicated with brown boxes over the residues.

CLUSTAL multiple sequence alignment by MUSCLE (3.8)

**Supplementary Figure 2. Multiple alignment of insulin receptor sequences.** Rhop-IR predicted aminoacid sequence (RPRC006251-PA) was aligned with 57 sequences of insulin receptors from 54 other species. Vertebrate (*Larimichthys crocea* XP\_019121818.1 and KKF23242.1, *Boleophthalmus pectinirostris* XP\_020784849.1, *Lates calcarifer* XP\_018533362.1, *Seriola lalandi dorsalis* XP\_023281132.1, *S. dumerili* XP\_022614011.1, *Pongo abelii* PNJ04174.1, *Pan troglodytes* XP\_016790340.1, *Dasypus novemcinctus* XP\_004477219.1, *Miniopterus natalensis* XP\_016072913.1, *H. sapiens* XP\_011526290.2, *Tupaia chinensis* XP\_014440404.1, *Callithrix jacchus* XP\_017823137.1, *Heterocephalus glaber* XP\_004865373.1) and invertebrate (*Cimex lectularius* XP\_014242610.1 and XP\_014242611.1, *Halyomorpha halys* XP\_014273072.1, *Zootermopsis nevadensis* KDR21367.1, *Trachymyrmex septentrionalis* XP\_018338965.1, *Atta colombica* KYM81501.1, *A. cephalotes* XP\_012056411.1, *Trachymyrmex cornetzi* KYN13503.1, *Camponotus floridanus* XP\_011251747.1, *Bombus terrestris* XP\_003393794.1, *B. impatiens* XP\_003490625.1, *Blattella germanica* CDI30232.1, *Cyphomyrmex costatus* KYN02366.1, *Acromyrmex echinatior* XP\_011051139.1, *Wasmannia auropunctata* XP\_011696537.1, *Vollenhovia emeryi* XP\_011864734.1, *Ooceraea biroi* XP\_011347281.1, *Cryptotermes secundus* PNF38775.1, *Dinoponera quadriceps* XP\_014476872.1, *Microplitis demolitor* XP\_014295647.1, *Linepithema humile* XP\_012228696.1 and XP\_012228695.1, *Neodiprion lecontei* XP\_015510416.1, *Pogonomyrmex barbatus* XP\_011648404.1, *Eufriesea mexicana* XP\_017754627.1 and XP\_017756280.1, *Orussus abietinus* XP\_023289633.1, *Athalia rosae* XP\_012260906.2, *Harpegnathos saltator* XP\_011144146.1, *Solenopsis invicta* XP\_011158641.1, *Melipona quadrifasciata* KOX70962.1, *Polistes dominula* XP\_015177172.1, *Dufourea novaeangliae* XP\_015431438.1, *Megachile rotundata* XP\_012136521.1, *Nasonia vitripennis* XP\_016838980.1, *Nicrophorus vespilloides* XP\_017772616.1, *Parasteatoda tepidariorum* XP\_015920989.1, *D. melanogaster* AAC47458.1, *O. nigriventris* AFQ20827.1, *Tribolium castaneum* AHF20214.1, *Nilaparvata lugens* AIY24638.1, *Apis mellifera* XP\_016773490.1) sequences were used. The region highlighted in yellow represents the extracellular portion of the receptor comprising the leucine-and cysteine-rich domains. The region highlighted in red indicates the intracellular tyrosine kinase domain, which was used to construct the phylogenetic tree. An asterisk (\*) indicates positions that have a single, fully conserved aminoacid residue, a colon (:) indicates conservation between aminoacid groups of strongly similar properties, and a period (.) indicates conservation between aminoacid groups of weakly similar properties.

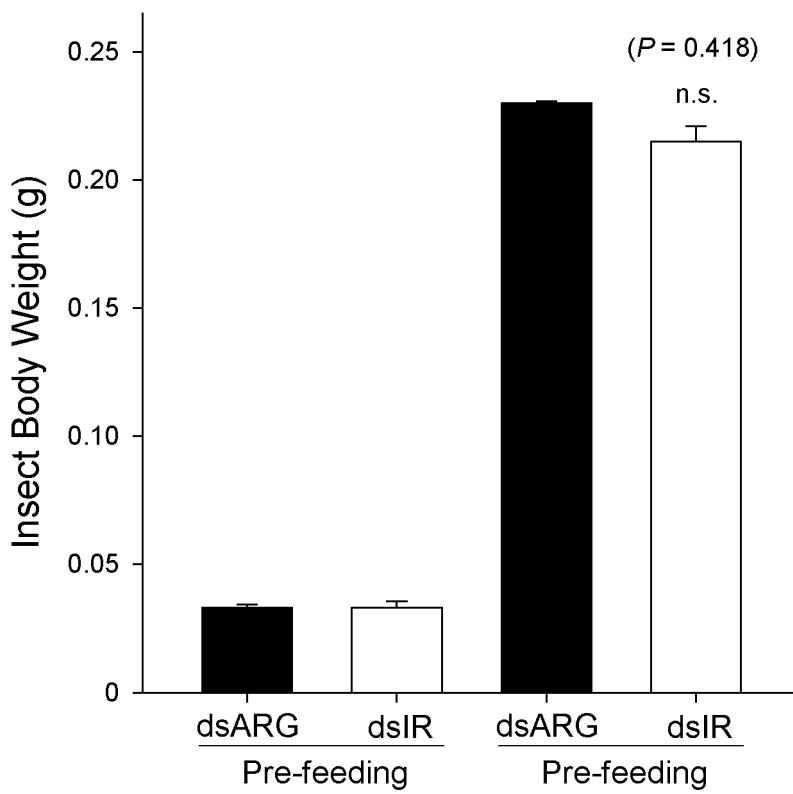

**Supplementary Figure 3. Semi-quantitative analysis of Rhopr-IR transcript expression in 5<sup>th</sup> instars.**

Unfed 5<sup>th</sup> instar *R. prolixus* were dissected and tissues were pooled into 6 different groups (CNS – central nervous system, AMG – anterior midgut, PMG – posterior midgut, HG – hindgut, FB – fat body, LM – leg muscles). (A) indicates Rhopr-IR transcript amplification and (B) indicates actin transcript amplification, which was used as a reference control. The experiment was repeated 3 times.

#### **Supplementary Figure 4. Analysis of Rhopr-IR transcript expression in 5<sup>th</sup> instars post dsRNA injection.**

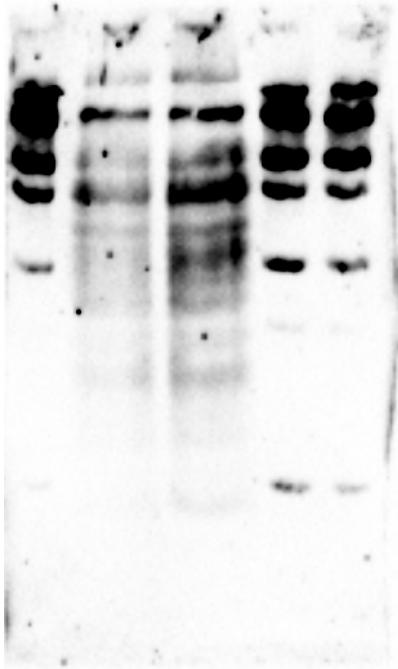

The double stranded RNAs for Rhopr-IR(dsIR) and Ampicillin Resistance Gene (dsARG) were injected into unfed 5<sup>th</sup> instar *R. prolixus* and insects were dissected at 3 and at 10 days post-injections. Tissues were pooled into 4 different groups (CNS – central nervous system, FB – fat body, LM – leg muscles, MG – midgut) and the expression of Rhopr-IR in dsIR-injected insects was quantified relative to the expression of Rhopr-IR in dsARG-injected insects by using qPCR and the  $\Delta\Delta Ct$  method (Pfaffl, 2001). The experiment was repeated 3 times and results are shown as means + std error.

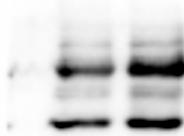

**Supplementary Figure 5. Post-feeding body weight of Rhopr-IR knockdown insects.** 5<sup>th</sup> instar *R. prolixus* were injected with 1  $\mu$ g of dsARG or dsIR in 1  $\mu$ L of ultrapure water and fed on defibrinated rabbit blood 3 days after injections. Insects were fed in groups of 40 individuals and allowed to feed for 25 minutes. Results are shown as means + std errors and the experiment was repeated for a total of 3 times. No statistical difference in post-feeding body weight was observed between dsARG- and dsIR-injected insects.

## Supplemental Data – Full Western blots

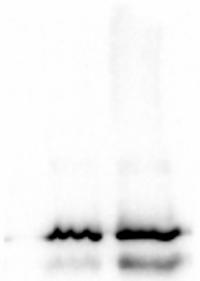

i. *Figure 4, BpV vs. Saline – Western blots probing for pTyr (a), actin (b), Akt (c), and pAkt (d)*

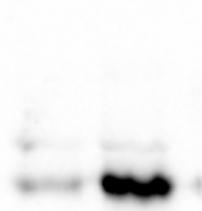

(a) Image displays chemiluminescent detection of anti-pTyr, using an anti-pTyr antibody, for blot shown in Figure 4. Some epitopes of proteins found within the ladders (lanes 1, 4 and 5) were also detected; it is possible that some of the proteins used in these ladders contain pTyr sites (information on proteins contained in protein ladders not disclosed by manufacturer).

(b) Image displays chemiluminescent detection of anti-actin, using an anti-B-actin primary antibody, for blot shown in Figure 4. Multiple bands observed, potentially as a result of different actin homolog variants within insects, or due to the detection of similar epitopes within different insect proteins. Bottom set of bands used as actin controls in Figure 4, based on MW identification of typical actin protein size in mammals (~42 kDa). Ladder not shown.

(c) Image displays chemiluminescent detection of anti-Akt, using an anti-Akt primary antibody, for blot shown in Figure 4. Multiple bands observed, potentially as a result of the detection of different Akt homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Top set of bands used as Akt protein signal, based on MW identification of typical Akt protein size in mammals (~60 kDa). Ladder not shown.

(d) Image displays chemiluminescent detection of anti-pAkt, using an anti-pAkt primary antibody, for blot shown in Figure 4. Multiple bands observed, potentially as a result of the detection of different pAkt homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Bottom set of bands used as pAkt protein signal, based on MW identification of typical pAkt protein size in mammals (~60 kDa). Ladder not shown.

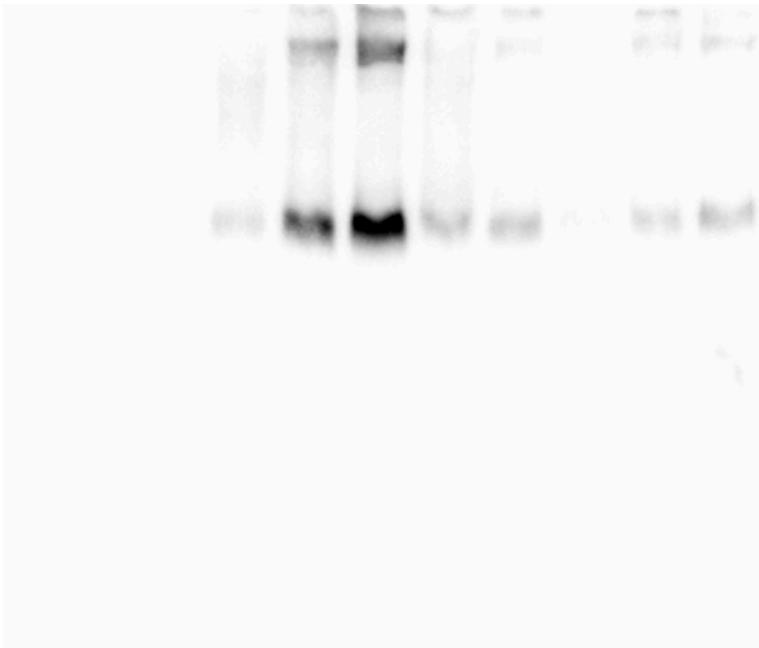

ii. *Figure 5A, weeklong feed experiment – pAkt (a), pGSK3B (b), pFOXO (c), and actin (d)*

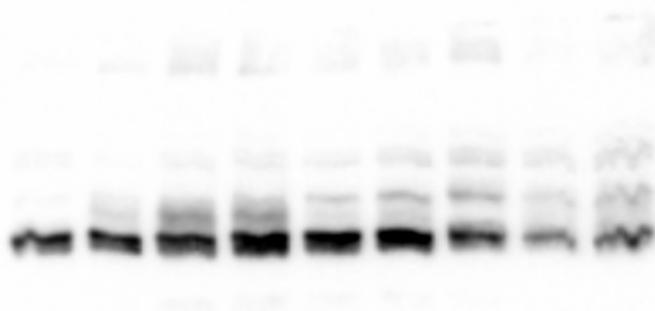

(a) Image displays chemiluminescent detection of anti-pAkt, using an anti-pAkt primary antibody, for blot shown in Figure 5A. Multiple bands observed, potentially as a result of the detection of different pAkt homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Bottom set of bands used as pAkt protein signal, based on MW identification of typical pAkt protein size in mammals (~60 kDa). Last two lanes not shown in Figure 5. Ladder not shown.

(b) Image displays chemiluminescent detection of anti-pGSK3B, using an anti-pGSK3B primary antibody, for blot shown in Figure 5A. Multiple bands observed, potentially as a result of the detection of different pGSK3B homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Bottom set of bands used as pGSK3B protein signal, based on MW identification of typical pGSK3B protein size in mammals (~46 kDa). Last two lanes not shown in Figure 5. Ladder not shown.

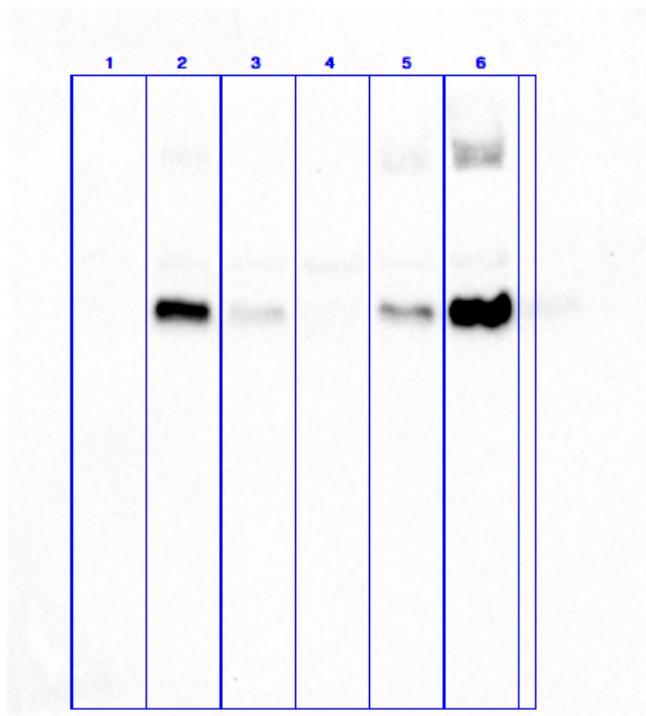

(c) Image displays chemiluminescent detection of anti-pFOXO, using an anti-pFOXO primary antibody, for blot shown in Figure 5A. Multiple bands observed, potentially as a result of the detection of different pFOXO homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Bottom set of bands used as pFOXO protein signal, based on MW identification of typical pFOXO protein size in mammals (~82 kDa). Last two lanes not shown in Figure 5. Ladder not shown.

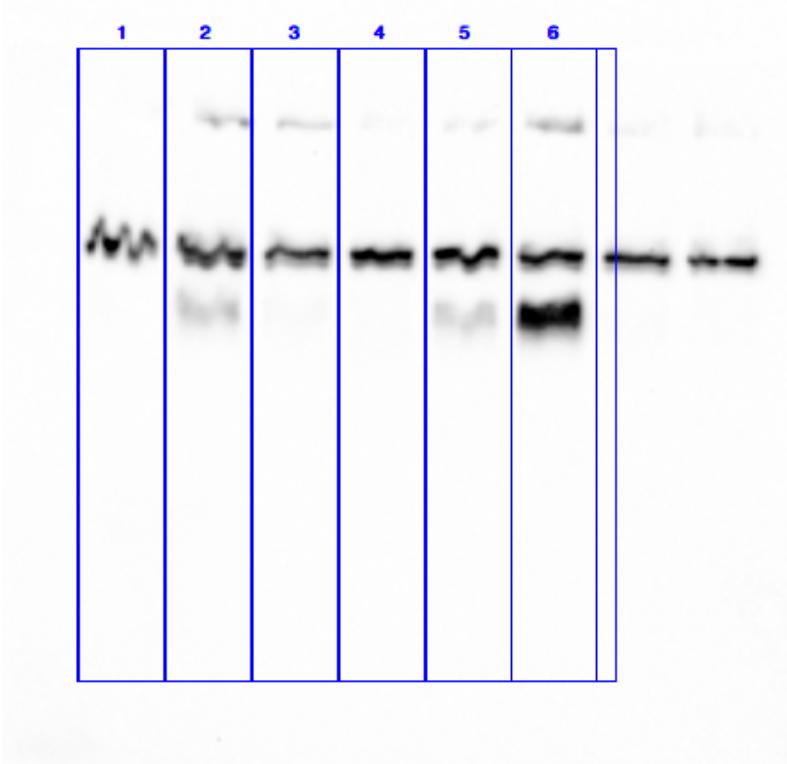

(d) Image displays chemiluminescent detection of anti-actin, using an anti-B-actin primary antibody, for blot shown in Figure 5A. Multiple bands observed, potentially as a result of the detection of different actin homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Bottom set of bands used as actin protein signal and control, based on MW identification of typical actin protein size in mammals (~42 kDa). Last two lanes not shown in Figure 5. Ladder not shown.

iii. Figure 7A, saline vs. porcine insulin – pAkt (a), and Akt (b)

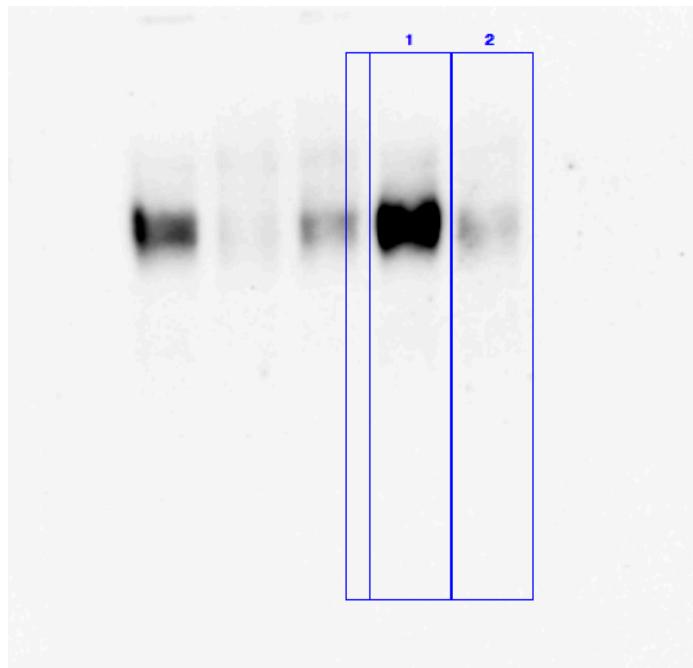

(a) Image displays chemiluminescent detection of anti-pAkt, using an anti-pAkt primary antibody, for blot shown in Figure 7A. Multiple bands observed, potentially as a result of the detection of different pAkt homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Bottom set of bands used as pAkt protein signal, based on MW identification of typical pAkt protein size in mammals (~60 kDa). Lanes correspond to the following conditions, as displayed in Figure 7A: Lane 1 = saline (- glucose); Lane 2 = saline (+ glucose); Lane 5 = porcine insulin (1 µg); Lane 6 = porcine insulin (0.1 µg). Ladder not shown. Lanes 3 and 4 not shown in Figure 7A.

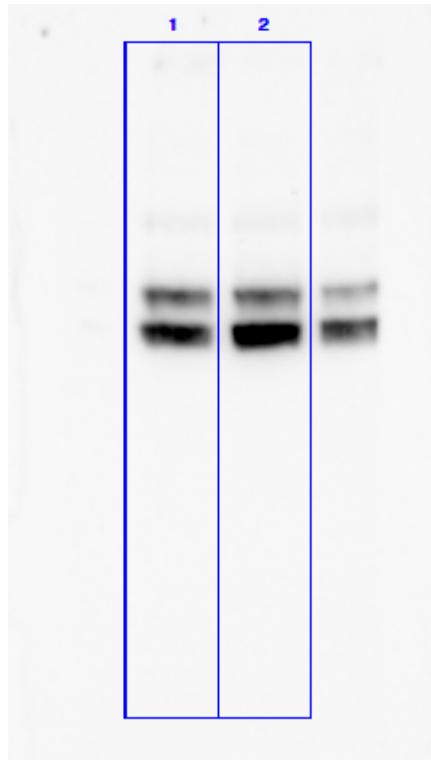

(b) Image displays chemiluminescent detection of anti-Akt, using an anti-Akt primary antibody, for blot shown in Figure 7A. Multiple bands observed, potentially as a result of the detection of different Akt homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Middle set of bands used as Akt protein signal, based on MW identification of typical Akt protein size in mammals (~60 kDa). Identified lanes correspond to the following conditions, as displayed in Figure 7A: Lane 1 = saline (- glucose); Lane 2 = saline (+ glucose); Lane 3 = human insulin (1 µg); Lane 4 = human insulin (0.1 µg); Lane 5 = porcine insulin (1 µg); Lane 6 = porcine insulin (0.1 µg). Ladder not shown. Lanes 3, 4, and last 2 lanes not shown in Figure 7A.

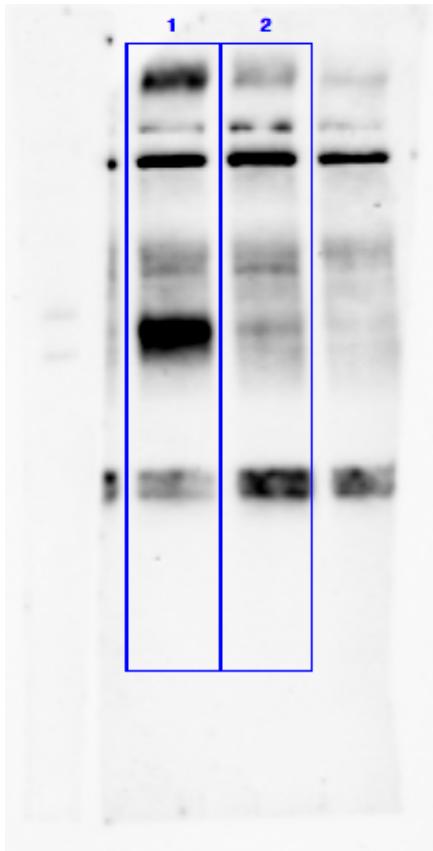

iv. *Figure 10, dsIR injections – pAkt (a), pGSK3B (b), pFOXO (c), and tubulin (d)*

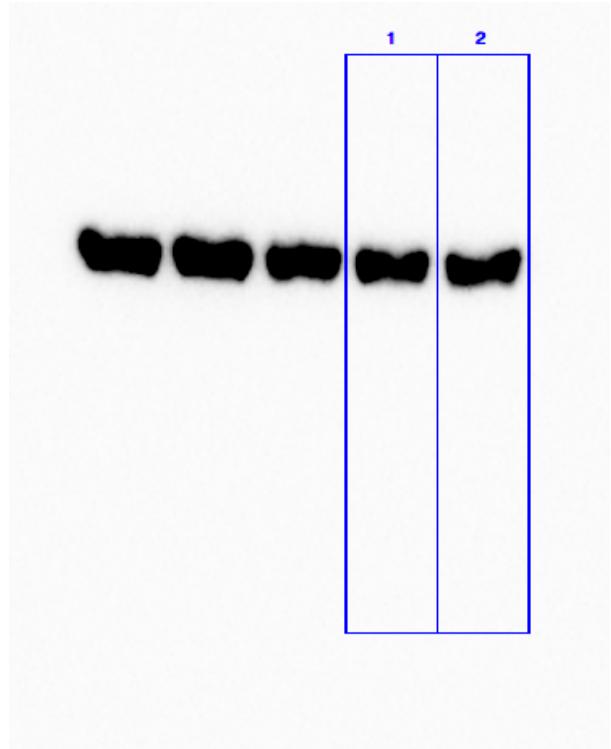

(a) Image displays chemiluminescent detection of anti-pAkt, using an anti-pAkt primary antibody, for blot shown in Figure 10. Multiple bands observed, potentially as a result of the detection of different pAkt homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Samples were obtained solely from fat bodies of unstimulated, starved 5<sup>th</sup> instar *R. prolixus*, unlike other blots shown in Figures 4, 5 and 7, and thus the propensity for detecting background noise is also higher since the signal intensity of pFOXO is inherently weaker without stimulation of the pathway by feeding or pharmacological intervention. Bottom set of bands used as pAkt protein signal, based on MW identification of typical pAkt protein size in mammals (~60 kDa). Identified lanes correspond to the following conditions, as displayed in Figure 10: Lane 1 = dsARG; Lane 2 = dsIR. Ladder not shown. Other lanes not used in Fig. 10.

(b) Image displays chemiluminescent detection of anti-pGSK3B, using an anti-pGSK3B primary antibody, for blot shown in Figure 5A. Multiple bands observed, potentially as a result of the detection of different pGSK3B homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Samples were obtained solely from fat bodies of unstimulated, starved 5<sup>th</sup> instar *R. prolixus*, unlike other blots shown in Figures 4, 5 and 7, and thus the propensity for detecting background noise is also higher since the signal intensity of pGSK3B is inherently weaker without stimulation of the pathway by feeding or pharmacological intervention. Bottom set of bands used as pGSK3B protein signal, based on MW identification of typical pGSK3B protein size in mammals (~46 kDa). Identified lanes correspond to the following conditions, as displayed in Figure 10: Lane 1 = dsARG; Lane 2 = dsIR. Ladder not shown. Other lanes not used in Fig. 10.

(c) Image displays chemiluminescent detection of anti-pFOXO, using an anti-pFOXO primary antibody, for blot shown in Figure 10. Multiple bands observed, potentially as a result of the detection of different pFOXO homologs that could be present in *R. prolixus*, or due to the detection of similar epitopes within different insect proteins. Samples were obtained solely from fat bodies of unstimulated, starved 5<sup>th</sup> instar *R. prolixus*, unlike other blots shown in Figures 4, 5 and 7, and thus the propensity for detecting background noise is also higher since the signal intensity of pFOXO is inherently weaker without stimulation of the pathway by feeding or pharmacological intervention. Middle set of bands used as pFOXO protein signal, based on MW identification of typical pFOXO protein size in mammals (~82 kDa). Identified lanes correspond to the following conditions, as displayed in Figure 10: Lane 1 = dsARG; Lane 2 = dsIR. Ladder not shown. Other lanes not used in Fig. 10.

(d) Image displays chemiluminescent detection of anti-tubulin, using an anti-a-tubulin primary antibody, for blot shown in Figure 10. Single set of bands used as tubulin protein signal control, based on MW identification of typical a-tubulin protein size in mammals (~50 kDa). Identified lanes correspond to the following conditions, as displayed in Figure 10: Lane 1 = dsARG; Lane 2 = dsIR. Ladder not shown. Other lanes not used in Fig. 10.
