## 1 Supplementary Text

### Text 1 | Mask calculation

To calculate cortical masks for the seed and target regions for the tractography, the T1 structural image was used for brain segmentation into white matter (WM) and grey matter (GM). The Freesurfer image analysis suite (<http://surfer.nmr.mgh.harvard.edu/>) was used for subsequent automatic cortical parcellation. The procedural details are given elsewhere (1). For M1, PMd and PMv, a surface-based cortical grey matter mask for the precentral gyrus was calculated based on the freesurfer parcellation labels 1024/2024 (left/right hemisphere). For SMA, we considered the superior frontal gyrus (labels 1028/2028). These large masks were transferred to FSL's MNI-T1 1mm standard space (by FLIRT/FNIRT registration) and used to calculate individual smaller masks for each motor area related to the white matter and grey matter boundary. For this, we considered both approved anatomical and connectivity based suggestions for the parcellation for whole M1 (2), SMA-proper (3) and PMd and PMv(4), as well as borders suggested by functional (5) and probabilistic cytoarchitectonic maps (6) in determining the extent of each cortical motor mask. For DLPFC, we decided to use Brodmann area (BA) 46 that is approximated as the middle third of medial frontal gyrus with the adjacent rostral portion of the inferior frontal gyrus and the middle frontal sulcus (7) (freesurfer labels 1109/2109, 1154/2154 and 1155/2155). The same extent was used in a previous analysis (8). For VLPFC, BA 44, 45 and 47 with the respective freesurfer labels 1018/2018, 1019/2019 and 1020/2020 were considered. The GM/WM boundary mask was calculated using FSL-FAST segmenting the individual T1 image into one GM and one WM binary mask. These masks were combined by thresholding each mask at 0.2, binarized, mean dilatated and finally multiplied with each other. The broad masks derived from Freesurfer were multiplied with this border mask and finally binarized. Then, all cortical masks were further multiplied with binarized and normalized FA maps with a threshold at >0.1 to provide seed/target voxels with a reasonable connection to major white matter trajectories. For M1, PMd, PMv and SMA we additionally included functional imaging data into the mask creation in order to bias the reconstruction of corticocortical connections toward the hand representations within each cortical motor area. Therefore, we used average peak coordinates from previously published functional MRI data (5) and selected the 500 nearest voxels adjacent to these coordinates within each GM/WM boundary masks (using an in-house Matlab script, Matlab R2010b, Mathworks, US, see supplementary table 2) resulting in smaller motor masks related to hand function and standardized in size and relation to the cortical GM/WM boundary. This information is adapted from our previous reports(8,9). A visualization of different steps of the mask creation can be found in supplementary Fig. 2 of Schulz et al., 2015.(8) An illustrative example of final individual seed/target masks is given in Fig. 3 below.

### Text 2 | Probabilistic tractography

For tractography, 25.000 streamlines were sent bi-directionally from both the seed and target regions. Interhemispheric und subcortical exclusion masks were used to guide this first step of the tract reconstruction. After equally combining both directions into one tract (10) and applying a threshold of 2%, the resulting trajectory was mean dilated four times including the seed and target masks. Based on

a refined exclusion mask derived from this procedure, to which additional exclusion voxels were added to avoid erroneous and spurious trajectories, such as corticofugal projections, a second tractography was conducted from both masks. According to a previous study (11), this procedure was found to allow for valid tract reconstruction of trajectories with - compared to others - small structural connectivity probabilities. Again, the connectivity distributions of both directions were combined. Four different levels (1%, 2%, 5% and 10%) were applied to the final output. For each threshold, the tract-related diffusion metrics were estimated and averaged across the thresholds for both the affected and unaffected hemispheres.

Tab. 2 | MNI coordinates of peak activation within cortical motor sites [Talairach-MNI converted] (5,12) Note that for DLPFC and VLPFC the whole extent of the mask was used during probabilistic tractography.

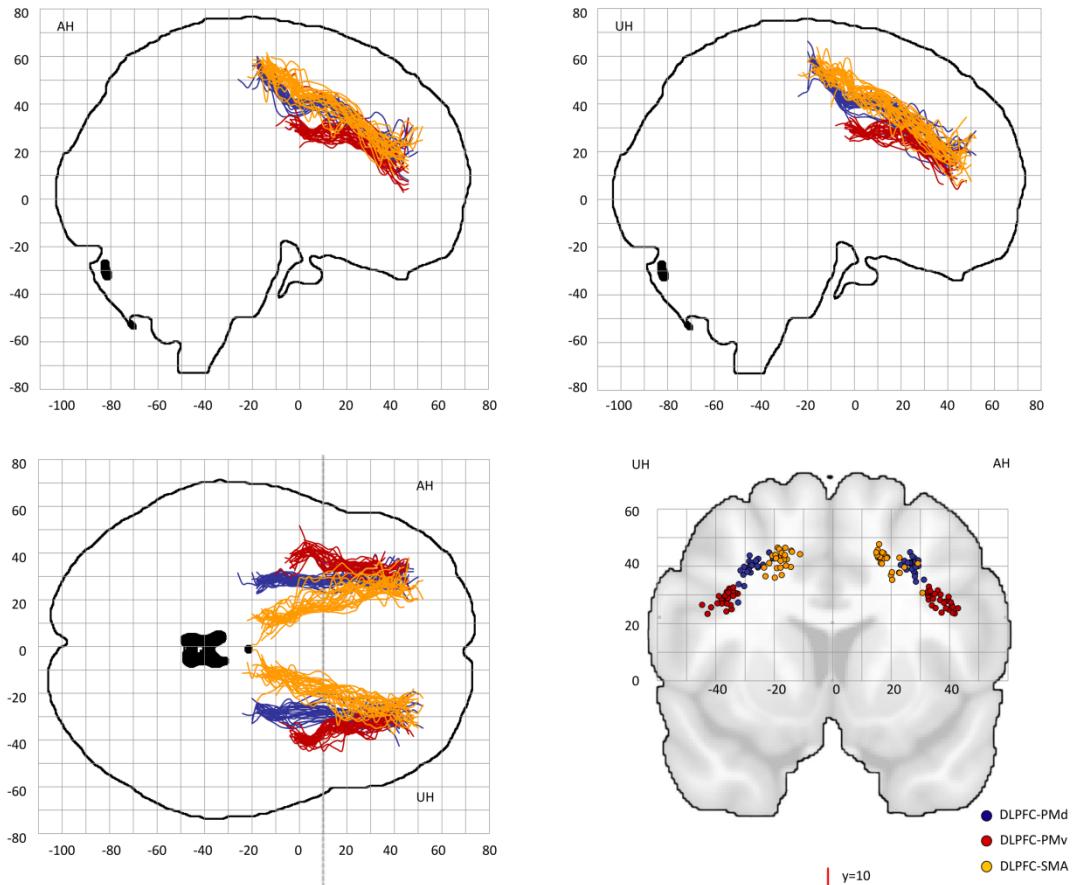

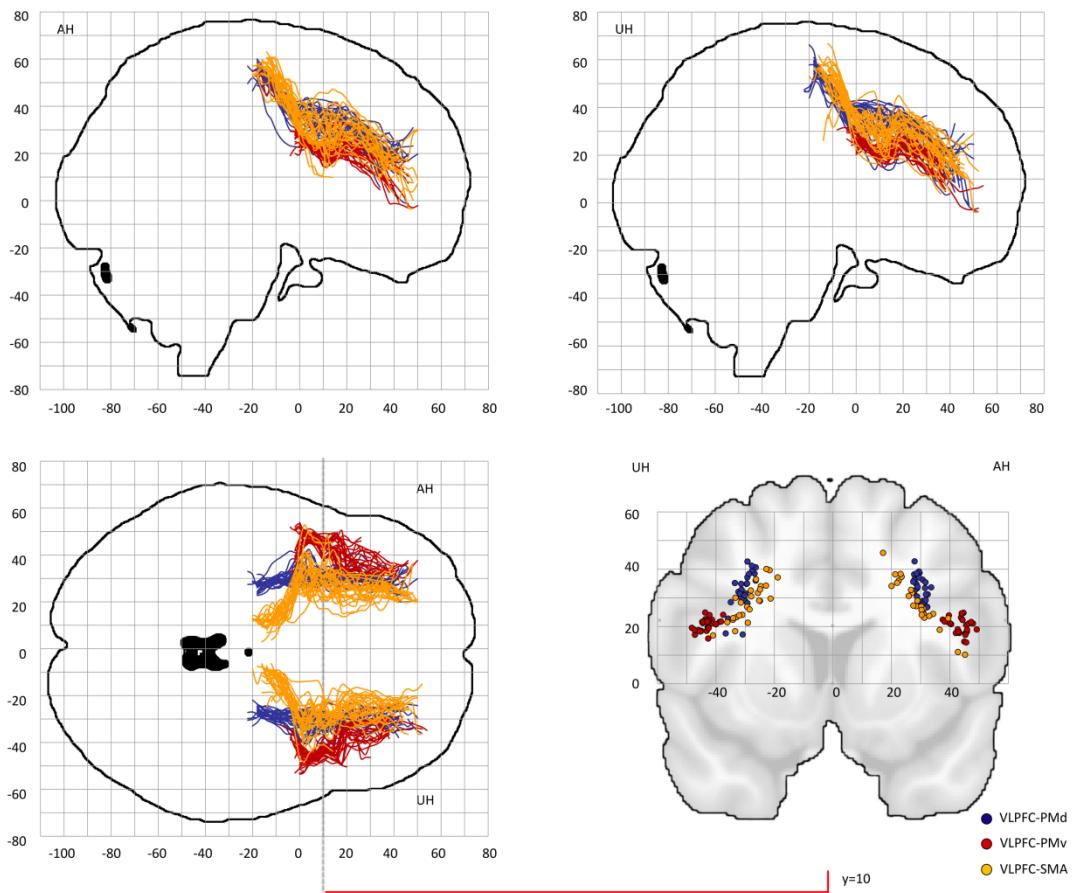

Fig. 1 | Centre of gravity analysis of prefrontal-premotor connections in healthy controls (DLPFC) The mean centre of gravity of all given tracts and patients was calculated from  $y=-40$  to  $y=70$  (MNI standard space) in 2 mm steps. Notably, only those  $y$ -values were presented in which more than two thresholds contributed to the final coordinate. All individual tracts are shown on two sagittal slices, one horizontal slice and one coronal slice at  $y=10$ . Table 2 provides statistics on the centre of gravity analysis at the coronal level. DLPFC = dorsolateral prefrontal cortex; PMd = dorsal premotor cortex; PMv = ventral premotor cortex; SMA = supplementary motor area.

Tab. 4 | Tract-related mean MD and residual motor output after stroke

Individual multiple linear regression models were estimated for each tract to test the relationship between tract-related mean MD values and the 4 parameter grip force (Grip), pinch force (Pinch) values, UEFM score and the composite score MO. Estimated coefficients of the tract-related MD values were adjusted for age, lesioned hemisphere (dominant or non-dominant), time after stroke and CST integrity and are given with 95% confidence intervals. P-values are derived from each model separately and were not corrected for multiple testing. Note that after correction for 48 models (13), none of the tracts reached the level of significance. Estimated coefficients of the 4 covariates are not shown for the sake of clarity. AH = affected hemisphere, UH = unaffected hemisphere. Asterisks indicate significant tracts.

Tab. 5 | Tract-related mean RD and residual motor output after stroke

Individual multiple linear regression models were estimated for each tract to test the relationship between tract-related mean RD values and the 4 behavioural parameter grip force (Grip), pinch force (Pinch) values, UEFM score and the composite score MO. Estimated coefficients of the tract-related RD values were adjusted for age, lesioned hemisphere (dominant or non-dominant), time after stroke and CST integrity and are given with 95% confidence intervals. P-values are derived from each model separately and were not corrected for multiple testing. Note that after correction for 48 models (13), none of the tracts reached the level of significance. Estimated coefficients of the 4 covariates are not shown for the sake of clarity. AH = affected hemisphere, UH = unaffected hemisphere. Asterisks indicate significant tracts.

Tab. 8 | Tract-related mean MD and residual motor output after stroke with stroke-lesion-size as additional covariate

Individual multiple linear regression models were estimated for each tract to test the relationship between tract-related mean MD values and the 4 parameter grip force (Grip), pinch force (Pinch) values, UEFM score and the composite score MO. Estimated coefficients of the tract-related MD values were adjusted for age, lesioned hemisphere (dominant or non-dominant), time after stroke, CST integrity and lesion size and are given with 95% confidence intervals. P-values are derived from each model separately and were not corrected for multiple testing. Note that after correction for 48 models (13), none of the tracts reached the level of significance. Estimated coefficients of the 5 covariates are not shown for the sake of clarity. AH = affected hemisphere, UH = unaffected hemisphere. Asterisks indicate significant tracts.

Tab. 9 | Tract-related mean AD and residual motor output after stroke with stroke-lesion-size as additional covariate

Individual multiple linear regression models were estimated for each tract to test the relationship between tract-related mean AD values and the 4 parameter grip force (Grip), pinch force (Pinch) values, UEFM score and the composite score MO. Estimated coefficients of the tract-related AD values were adjusted for age, lesioned hemisphere (dominant or non-dominant), time after stroke, CST integrity and lesion size and are given with 95% confidence intervals. P-values are derived from each model separately and were not corrected for multiple testing. Note that after correction for 48 models (13), none of the tracts reached the level of significance. Estimated coefficients of the 5 covariates are not shown for the sake of clarity. AH = affected hemisphere, UH = unaffected hemisphere. Asterisks indicate significant tracts.

Tab. 10 | Tract-related mean RD and residual motor output after stroke with stroke-lesion-size as additional covariate

Individual multiple linear regression models were estimated for each tract to test the relationship between tract-related mean RD values and the 4 parameter grip force (Grip), pinch force (Pinch) values, UEFM score and the composite score MO. Estimated coefficients of the tract-related RD values were adjusted for age, lesioned hemisphere (dominant or non-dominant), time after stroke, CST integrity and lesion size and are given with 95% confidence intervals. P-values are derived from each model separately and were not corrected for multiple testing. Note that after correction for 48 models (13), none of the tracts reached the level of significance. Estimated coefficients of the 5 covariates are not shown for the sake of clarity. AH = affected hemisphere, UH = unaffected hemisphere. Asterisks indicate significant tracts.
