Experimental details

The experiments were conducted with 14 wheat (*Triticum aestivum* L.) cultivars from Serbia (5), Austria (4) and Azerbaijan (5), which were grown under four different water/salt treatment (T) conditions:

T1- Well watered (60 % soil water capacity) and no salt (NaCl) added,

T2- Water limited (20 % soil water capacity) and no salt (NaCl) added,

T3- Well watered (60 % soil water capacity) and saline conditions (0.2% NaCl, i.e. 2g /kg soil),

T4- Water limited (20 % soil water capacity) and saline conditions (0.2% NaCl, i.e. 2g /kg soil).

At the end of the experiment (13 weeks after the stress treatments were started) biomass and grain production parameters (total above-ground mass, grain yield) were determined.

Gas exchange parameters: CO₂ uptake rate, transpiration, stomatal conductance and intercellular CO₂ concentration were measured by using a Licor 6400 gas analyzer (Licor, USA). Two to three selected pieces of attached leaves from plant replicates under respective treatments were inserted into the gas cuvette for individual measurements (Paul et al., 2016). The gas cuvette conditions were set to 400 ppm CO₂, ambient temperature and growth light intensity of photosynthetic active radiation (400 μmol photons m⁻² s⁻¹).

Electron transport rate of photosystem II (ETR II): ETR(II) was monitored by using a Mini PAM photosynthesis yield analyzer (WALZ, Effeltrich, Germany). The measurements were performed on the last fully developed leaf, denoted as ‘flag leaf’ (Paul et al., 2016) in the 6th and 7th week after the start of the stress treatments. The apparent rate of electron transport was calculated as $ETR(II) = Y(II) * PPFD * 0.5 * 0.84$ (Genty et al., 1989), where Y(II) is the effective quantum yield of PSII, PPFD is the photon flux density of incident photosynthetically active radiation. The two coefficients (0.5 and 0.84) represent the fraction of absorbed light partitioned to PSII, and the probability that the

incident irradiance will be absorbed by PSII in higher plants, respectively (Björkman and Demmig, 1987; Schreiber, 2004).

Proline content determination: Fresh leaf samples (0.1 g from the fully developed leaf below the flag leaf) were collected from all studied wheat cultivars and stored in liquid nitrogen. The content of free proline was determined as described earlier (Bates et al., 1973) at the 10th week after the start of the stress treatments. Samples were homogenized in 3% (w/v) sulfosalicylic acid to precipitate protein, and centrifuged at 14,000xg for 10 min. The reaction mixture contained 2 mL glacial acetic acid, 2 mL ninhydrin reagent (2.50 % w/v ninhydrin in 60 % v/v 6 M phosphoric acid) and 2 mL of the supernatant. The incubation lasted for 1 h at 90 °C then, after stopping the reaction with ice, 4 cm³ of toluene was added and vortexed. The upper toluene phase was decanted into a glass cuvette and absorbance was measured at $\lambda = 520$ nm. Each assay was performed in five replicates representing five leaves from different plants for each treatment. The content of proline was expressed as mg g⁻¹ fresh weight according to a calibration curve with proline.

Soil properties: A mixture of Terra peat soil and sandy soil (3:1, v/v) was used for the experiments, with 0.9 kg/dm³ specific gravity. Water retention curve was determined according to MSZ-08-0205:1978 by using pF box between at pF 0-2.5 (0.1 -31.6 kPa), pressure membrane extractor at pF 4.2 (1584.9 kPa) and vapor equilibrium technique above that. The measurements were performed by the accredited Soil Safety Laboratory of the National Food Chain Safety Office, Velence, Hungary.

Statistical analysis:

Calculation of mean and SD, tests for normal distribution of data, one-way ANOVA analysis of the significance level between mean differences, as well as heteroscedasticity tests for the distribution of residuals for the linear regression of data were performed by the XLSTAT-Premium software package (Addinsoft (2019), Boston, USA. <https://www.xlstat.com>).

Supplementary Figure 1. Water retention curve of the soil used for the experiments. The measurements were performed in the 3:1 (V/V) mixture of peat and sand without addition, and in the presence of 2 g/kg NaCl. The data represent the means and SD of 5 different soil samples at pF 0, 1.5, 2.0 and 2.5. In case of the pF 4.2 and 6.2 points only one measurement of the no salt and of the 2g/kg samples was successful. The pF values are expressed in cm, that is why the values in kPa are 10-fold smaller. The dashed lines indicate 60% and 20% soil water capacity (considering the 0.9 kgL⁻¹ specific gravity of the soil), which correspond to -3 (well watered) and -3500 kPa (water limited) soil water potential, respectively. Statistical analysis of the data is shown in Supplementary Table 1.

Supplementary Figure 2. Correlation of dry biomass and grain yield obtained under water limited versus saline and saline plus water limited conditions. A, Total dry biomass values obtained under well watered plus salt (T3), and water limited plus salt (T4) conditions are plotted as a function of total dry biomass obtained under water limited (T2) conditions. B, The same as A, but total grain yield is plotted. The shape of the symbols corresponds to the treatments, while the color code represents the different cultivars. Data shown are mean of $n=5$ plants/treatment. The red solid lines represent the best fitting linear correlation curves for each of the four treatments with the indicated Pearson's R^2 values.

Supplementary Figure 3. Correlation of relative tolerance of dry biomass and grain yield obtained under water limited versus saline, and saline plus water limited conditions. Relative stress tolerance, or yield stability, was calculated as the ratio of total above ground biomass (or grain yield) obtained under stress and the well watered control conditions. A, Salinity tolerance of dry biomass is plotted as function of drought tolerance of dry biomass under well watered plus salt (T3), and water limited plus salt (T4) conditions. B, The same as A, but total grain yield tolerance values are plotted. The shape of the symbols corresponds to the treatments, while the color code represents the different cultivars. Data shown are mean of $n=5$ plants/treatment. The red solid lines represent the best fitting linear correlation curves for each of the four treatments with the indicated Pearson's R^2 values.

Supplementary Figure 4. Correlation of the net rate of photosynthesis with stomatal conductance. Net rate of photosynthesis (CO_2 uptake) is plotted as a function of stomatal conductance, both obtained from gas exchange measurements. The data obtained for the 14 selected wheat cultivars under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data shown are mean $\pm$ SE ($n=5$) plants/treatment.

Supplementary Figure 5. Effect of salt and drought stress on the electron transport rate through Photosystem II. ETR(II) was determined as described in the Materials and Methods as a function of light intensity and shown for two selected cultivars. The measurements were performed under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data shown are mean $\pm$ SE ($n=5$) plants/treatment.

Supplementary Table 1. Data (% V/V) shown are the mean and SD of soil water content (n=5 samples/treatment). Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the $p > 0.05$ values show normal distribution of data, while in the ANOVA table the $p < 0.05$ show that the corresponding means are different at 5% significance level.

Supplementary Table 3. Effect of drought and salt stress on projected leaf area of wheat plants. Measurements were performed under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data (cm²) shown are the mean and SD (n=5 plants/treatment) of leaf area values obtained for the last three measurement days (in the 55-71 days range). Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the p>0.05 values show normal distribution of data, while in the ANOVA table the p<0.05 show that the corresponding means are different at 5% significance level.

Supplementary Table 4. Effect of drought and salt stress on dry biomass of wheat plants.

Measurements were performed under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data (g) shown are the mean and SD (n=5 plants/treatment). Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the $p > 0.05$ values show normal distribution of data, while in the ANOVA table the $p < 0.05$ show that the corresponding means are different at 5% significance level.

Supplementary Table 5. Effect of drought and salt stress on grain yield of wheat plants.

Measurements were performed under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data (g) shown are the mean and SD (n=5 plants/treatment). Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the $p > 0.05$ values show normal distribution of data, while in the ANOVA table the $p < 0.05$ show that the corresponding means are different at 5% significance level.

Supplementary Table 6. Effect of drought and salt stress on harvest index of wheat plants.

Measurements were performed under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data shown are the mean and SD (n=5 plants/treatment). Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the $p > 0.05$ values show normal distribution of data, while in the ANOVA table the $p < 0.05$ show that the corresponding means are different at 5% significance level.

Supplementary Table 7. Effect of drought and salt stress on water use of wheat plants.

Measurements were performed under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data for the total amount (mL) of water used during the experiment shown are the mean and SD (n=5 plants/treatment). Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the $p > 0.05$ values show normal distribution of data, while in the ANOVA table the $p < 0.05$ show that the corresponding means are different at 5% significance level.

Supplementary Table 8. Effect of drought and salt stress on net photosynthesis rate in wheat

plants. Gas exchange measurements were performed by a Licor 6400 gas analyzer under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data ($\mu\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$) shown are the mean and SD (n=12-14 measurements).

Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the $p > 0.05$ values show normal distribution of data, while in the ANOVA table the $p < 0.05$ show that the corresponding means are different at 5% significance level.

Supplementary Table 10. Effect of drought and salt stress on internal CO₂ concentration in

wheat plants. Gas exchange measurements were performed by a Licor 6400 gas analyzer under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data (mol H₂O m⁻² s⁻¹) shown are the mean and SD (n=12-14 measurements).

Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package.

In the normality tests the p>0.05 values show normal distribution of data, while in the ANOVA table the p<0.05 show that the corresponding means are different at 5% significance level.

Supplementary Table 12. Proline content (mg g⁻¹ fresh weight) of wheat leaves. Measurements were performed under well watered (T1), water limited (T2), salt plus well watered (T3), and salt plus water limited (T4) conditions. Data shown are mean± SE (n=3-5) plants/treatment. Calculation of mean and SD, tests for normal distribution of data, and one-way ANOVA analysis of the significance level between mean differences was performed by the XLSTAT software package. In the normality tests the p>0.05 values show normal distribution of data, while in the ANOVA table the p<0.05 show that the corresponding means are different at 5% significance level.
