**Supplementary material:** The following information is provided (a) methodological details regarding the estimation of low and high fishing pressure sites for small-scale fisheries, (b) site codes, geographic coordinates, and geographic location (Table S1), (c) density and biomass values of the different fish species recorded per fishing pressure and depth zone (Tables S2 , S3), (d) results of the SIMPER analysis (Tables, S4, S5, S6), (f) charts of the cluster analyses (Figure S1, S2), (f) charts illustrating the size structure of commercial fish species per level of fishing pressure (Figure S3).

**Details on the method used to estimate cold (low) and hot (high) spots of small-scale fishing pressure.**

Based on methods for analyzing spatial patterns and mapping clusters (Fortin and Dale, 2005; Maina et al., 2018), hot and cold spots of small-scale fishing pressure (i.e. areas of high and low FP) were estimated. In particular, the Ripley's K function was used to explore the overall scale of clustering (Ripley, 1975), and the Global Moran's I statistic for a series of increasing distances was used to measure the intensity of spatial clustering for each distance (Moran, 1950). Moreover, the Getis-Ord Gi\* statistic (Getis and Ord, 1992) was applied to the layers of small-scale FP of the study area, in order to identify statistically significant hot and cold spots. The analysis was performed using the ESRI's ArcGIS v10.4 spatial statistics tools (ESRI, 2015). The Ripley's K function indicated that the spatial clustering was statistically significant at distances <816 km, while the most appropriate scale to be used in Getis-Ord Gi\* statistic, estimated by Global Moran's I, was 26 km. Finally, the Getis-Ord Gi\* statistic showed whether features with high or low FP values tend to be clustered in the study area (Fig. 1).
