**Figure S3.** 2D HSQC NMR of treated sample.

Figure S4. FTIR spectrum of rearrangement product (Reaction condition: 80°C, in n-hexane, TMEDA/n-BuLi=1:1, the molar ratio of n-BuLi to C=C is 1:1).

4 Preparation and Analysis Procedures for Samples in Figure 1 and Table 1

Materials & Characterizations. TMEDA was purchased from Sigma-Aldrich Chemical Co. and freshly distilled in the presence of CaH. n-Hexane was distilled in the presence of Na/K and benzophenone under a dry N_2 atmosphere. n-Butyllithium (2.5 mol/L in hexane), methanol, and 2,6-di-tert-butyl-4-methylphenol were obtained from Energy Chemical and used without further purification. Polybutadiene (Grade: BR9000. 1,4-cis > 97%, determined by FTIR spectroscopy.) was supplied from Sinopec Qilu Petrochemical Company and used without further purification. ^{1}H NMR and 2D HSQC NMR were measured on a Bruker Avance 500M spectrometer in CDCl$_3$ at 30°C. FTIR spectra were recorded on a Bruker Tensor II FTIR spectrometer. Conjugated double bond content was quantitatively determined by ^{1}H NMR integration, the equation employed for the calculation is shown as follows.

$$C.\,content = \frac{I(5.74{\sim}6.62)}{I(5.74{\sim}6.62) + I(5.4) + I(4.99)} \times 100\%$$

Sample preparation. The typical sample preparation procedure was as follows: A certain amount of polybutadiene/n-hexane solution (0.067 g/mL), TMEDA, and n-BuLi were added sequentially into a glass reactor under a nitrogen atmosphere. After heating in a water bath at a given temperature for a given time, methanol containing 2,6-di-tert-butyl-4-methylphenol (1.0 wt%) was added to quench the reaction. The reaction product was washed several times with 10% dilute hydrochloric acid and water to remove the lithium salt and remaining TMEDA. The organic layer was separated and dried with MgSO$_4$, then the suspension was filtered, and the filtrate was evaporated under vacuum.

Computational details. Considering that the polymer contains too many atoms, making it difficult to calculate, we designed an oligomer containing only a few structural units as a model, thus simplifying the calculation. The DFT calculations were implemented by ORCA 4.2.1 program package (Neese 2011). The equilibrium geometry of the model was optimized by using DFT methods at the B3LYP/6-31G(d,p) level (Lee, Yang et al. 1988). The frequency calculation was performed to characterize the minimum structure as a stable point on the potential energy surface (no imaginary frequency). The ESP analysis was performed with the Multiwfn 3.7 program (Lu and Chen 2012). The visualization of the ESP map was performed with Avogadro 0.9.5 (Hanwell, Curtis et al. 2012) and Jmol 14.31.27 (Howard 2013). Besides, POV-Ray software was employed for 3D rendering to obtain higher resolution images.
