

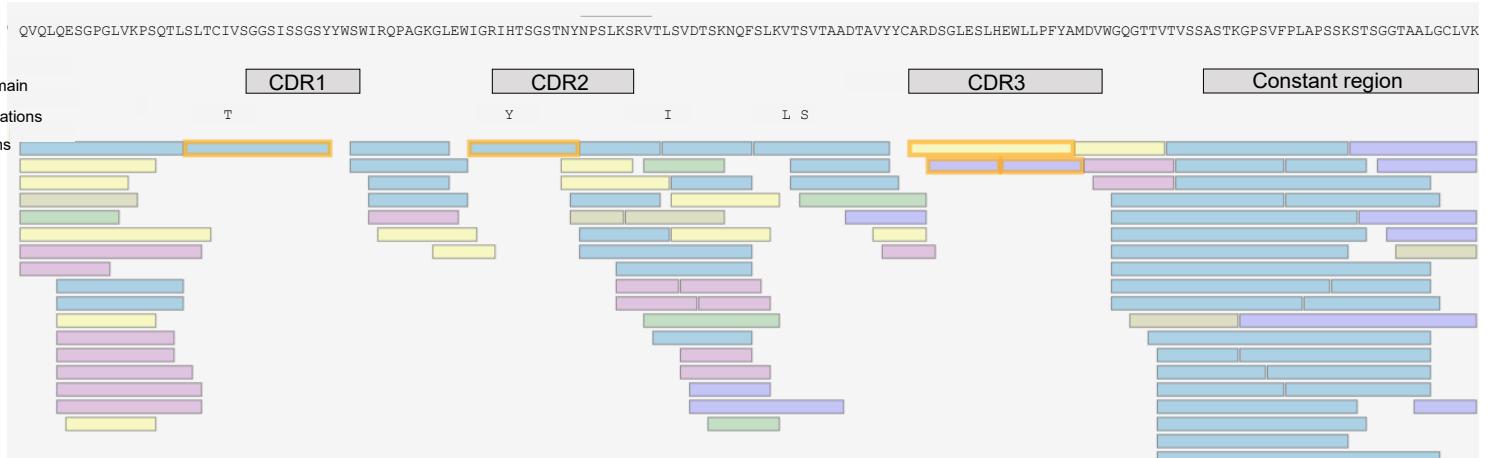

Figure S1

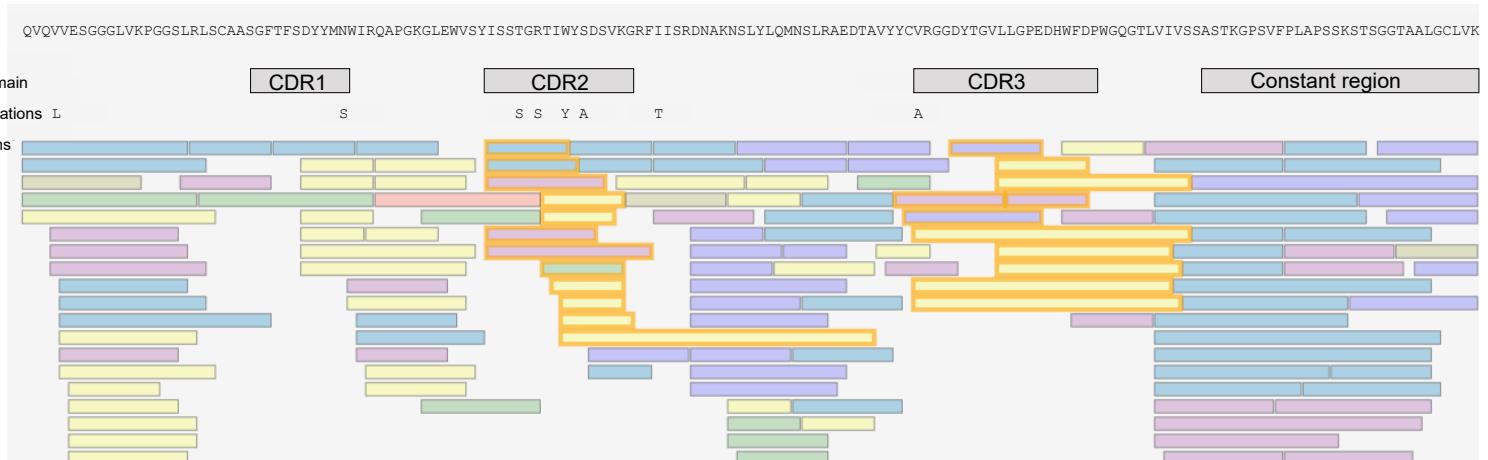

A

EBOV-1130

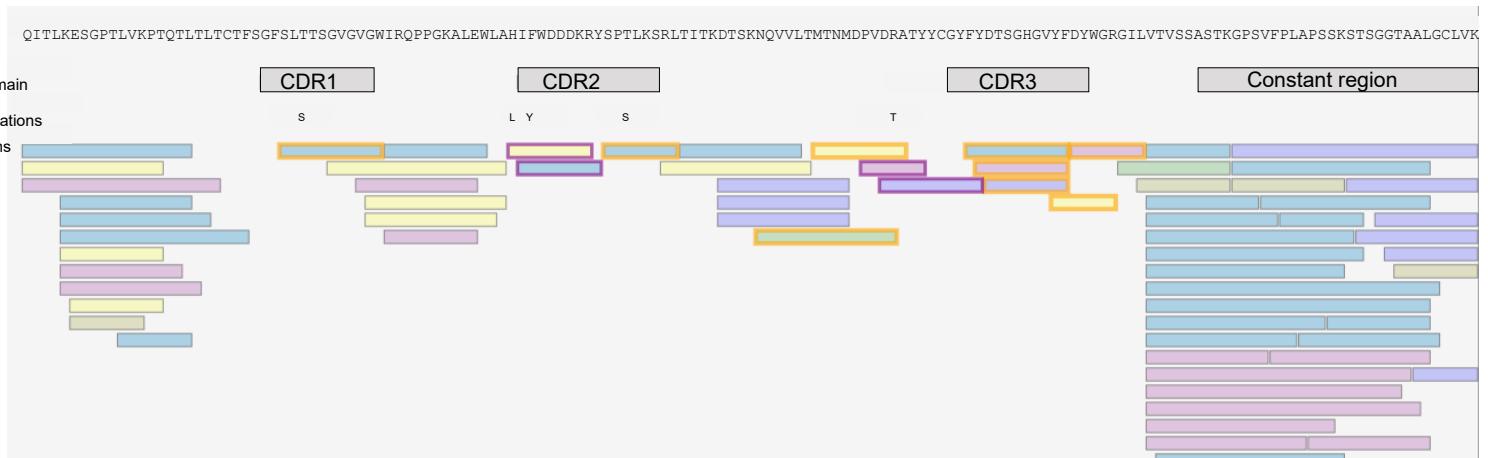

B

EBOV-1131

C

EBOV-1181

Supplementary Figure 1. Identification of mAb sequences in convalescent plasma using proteo-genomics analysis. Peptide coverage maps that were created for each of three memory B cell sequences ([**panel A**] EBOV-1130; [**panel B**] EBOV 1131; [**panel C**] EBOV-1181) by searching the mass spectra against memory B cell sequences dataset are shown. Alicanto analysis software was used to generate maps of peptide coverage; maps of three identified heavy chain variable region sequences are shown as examples. The germline residues for the classified variable gene identifications (defined as “Mutations”) and positions of CDR1, CDR2, or CDR3 regions (defined as “Domain”) are shown. Each identified spectrum was assigned a peptide sequence defined as peptide-spectrum matches (PSMS), and identical peptides are represented by a single box. The color of each rectangle corresponds to the enzymatic cleavage reaction from which that peptide originated: trypsin (green), chymotrypsin (light blue), pepsin (light pink), elastase (yellow), ArgC (tomato/dark pink), LysC (olive), or GluC (dark red). Gold outline of the rectangle indicates the peptide maps that are unique to that single antibody variable region sequence. The peptide maps unique to that antibody CDR1-CDR3 clone (*i.e.*, concatenating CDR1+CDR3 and uniquely clustering on those regions define the CDR1-CDR3 clone) are shown with purple outline.

Supplementary Table 2. Peptides for CDR3 of heavy and light chain variable regions identified by proteo-genomic approach
