

Supplementary Figures and Tables:

Supplementary Figure S1. Multiple sequence alignment with the IL17 domain of a representative sequence from each IL-17 mussel isoform. Conservation of each position is represented. The cysteine knot fold motif that distinguish the conserved structure of IL-17 is maintained in every sequence.

**Supplementary Figure S2. Neighbor joining phylogenetic analysis of different selected species.** Sequences from the repertoires of selected Chordata species (*Homo sapiens*, *Mus musculus*, *Danio rerio*, *Salmo salar*) and Mollusca species (*Mytilus galloprovincialis*, *Crassostrea gigas*, *Biomphalaria glabrata*, *Octopus bimaculoides*) were submitted to phylogenetic analysis. Results evidence the lack of homolog sequences between different phyla. The tree is clustered by phyla/species and not by isoform. Clustering by isoform can be only observed when working only with phylogenetically close IL-17 repertoires, with homolog genes.

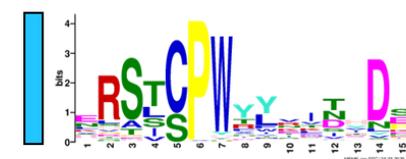

Motif	Symbol	Motif Consensus

2.		ERSTCFWYVIITHDS
3.		YPPSJTEAVCRRCGC

Motif 1

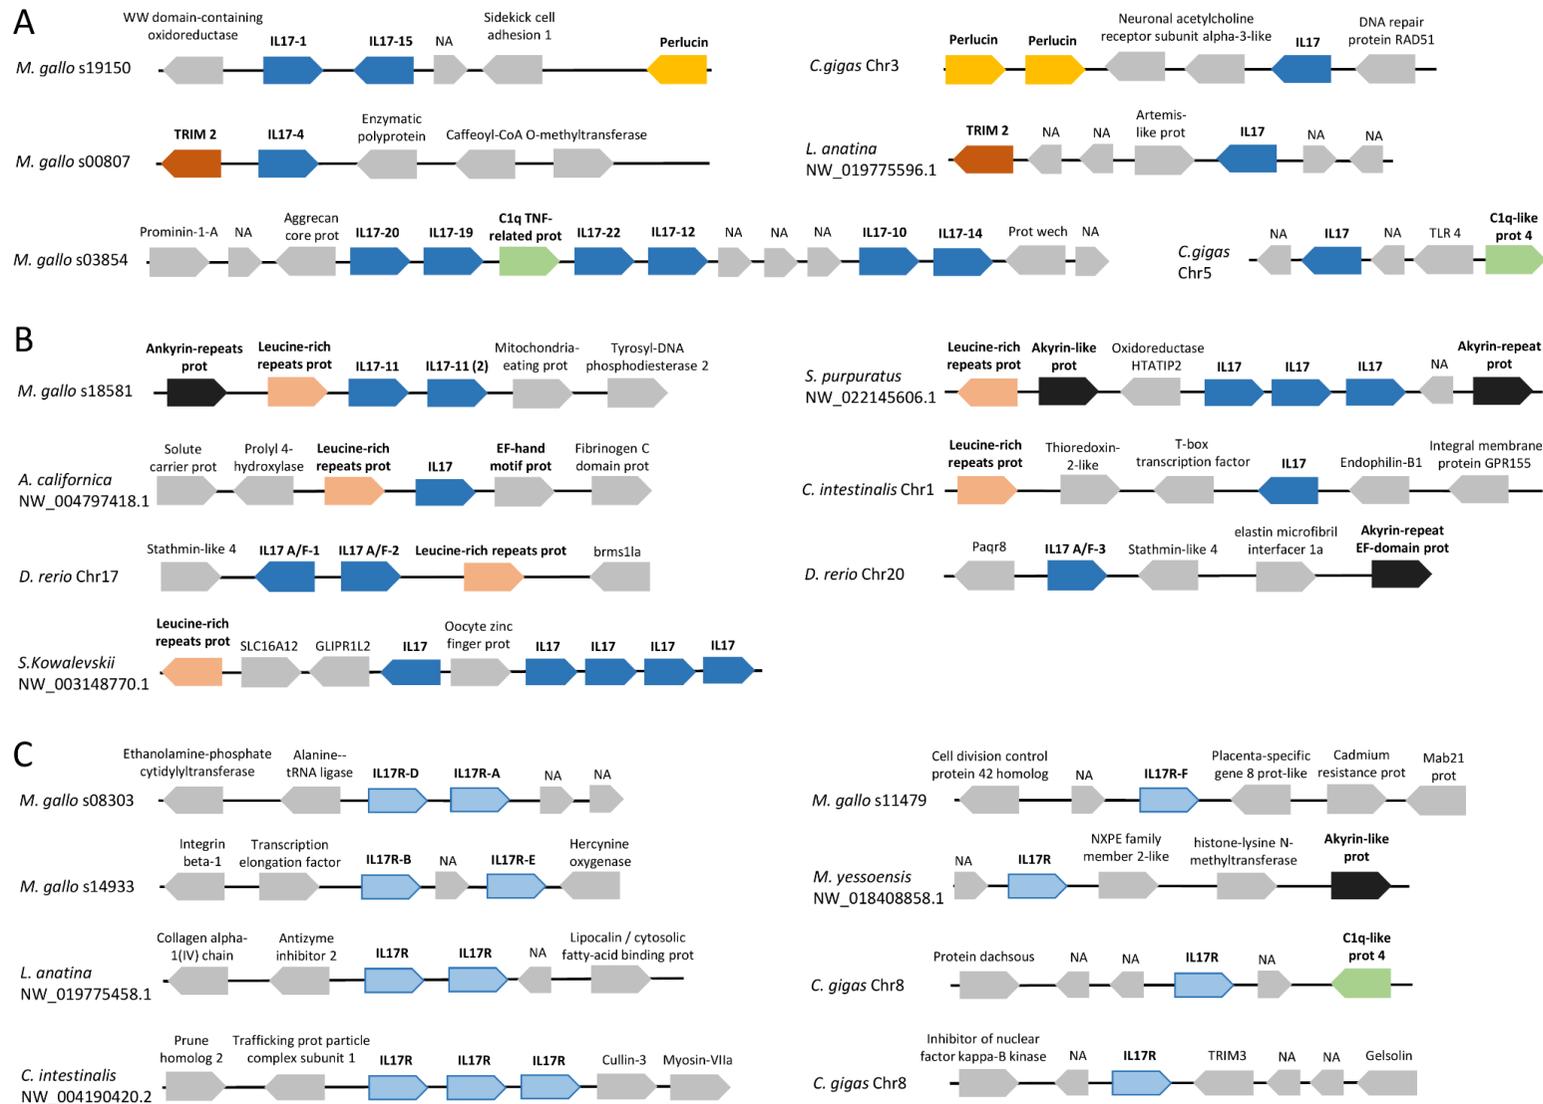

Motif 2

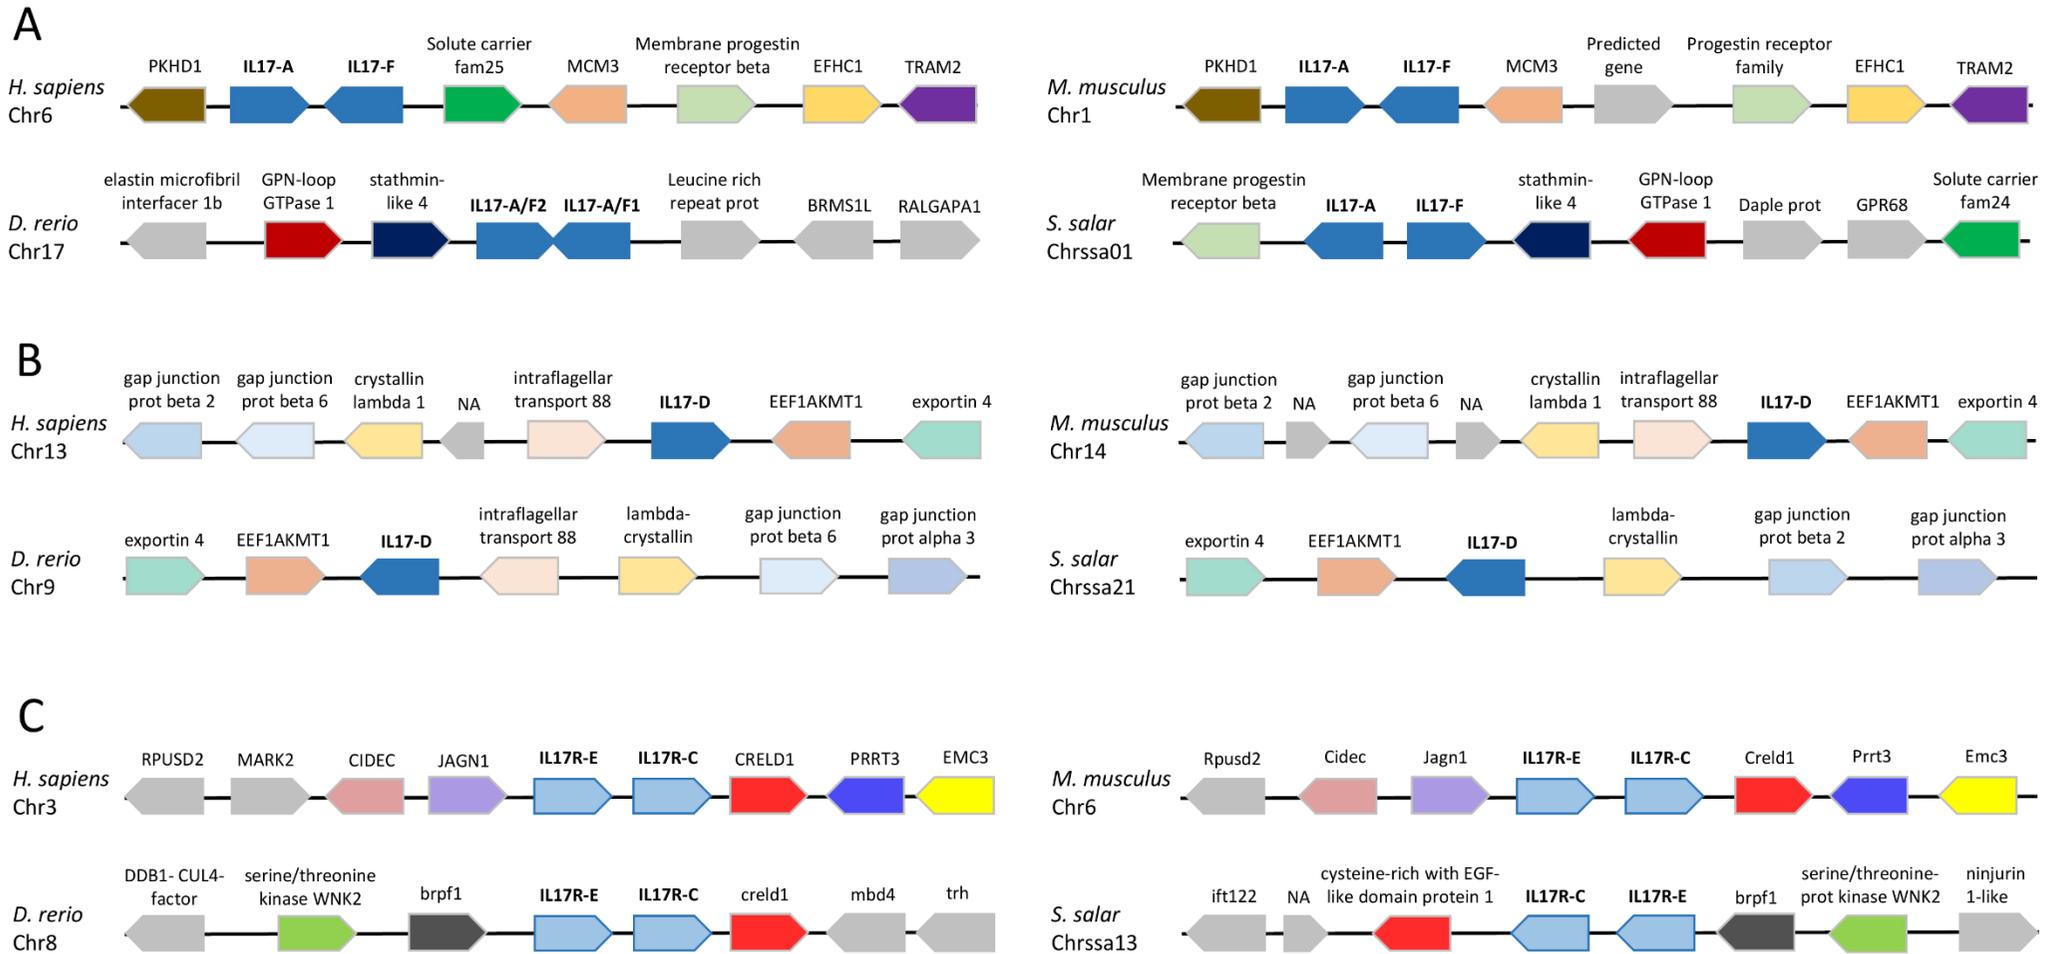

Motif 3

**Supplementary Figure S3. Conserved motif analysis in representative sequences of IL-17 isoforms different selected species.** Although the amino acid identity is low between sequences from different phyla, there is a great conservation at the motif level, relative to the functional IL-17 domain region. Conserved motif logos show the defining cysteine pattern and a conserved motif consisting in CPW in invertebrate sequences and SPW in chordate species.

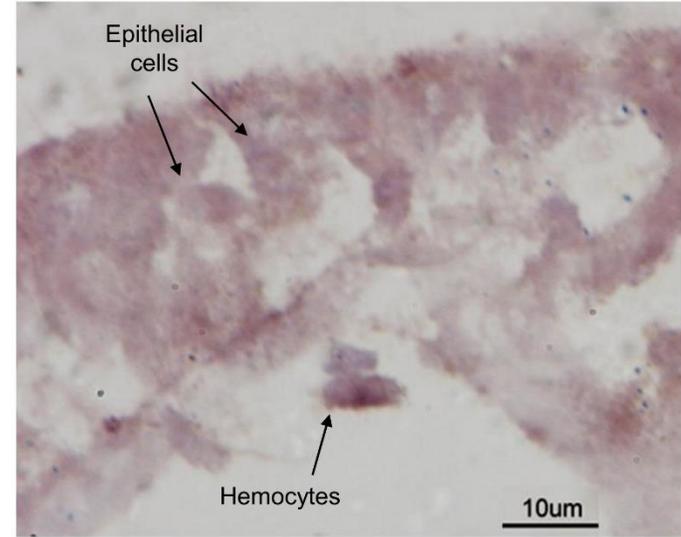

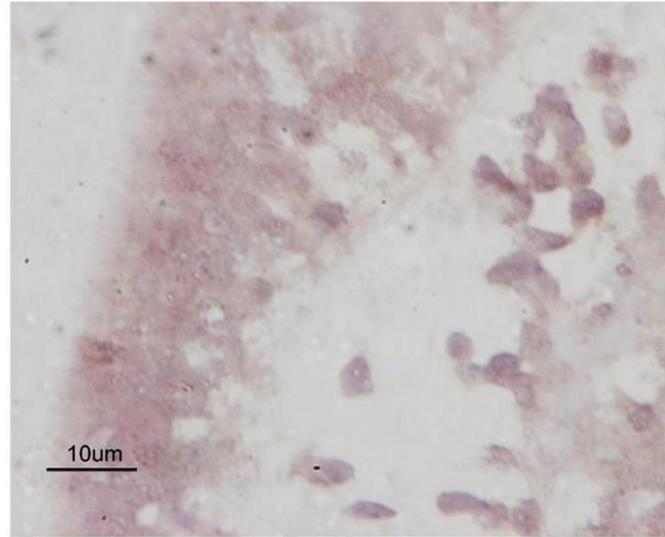

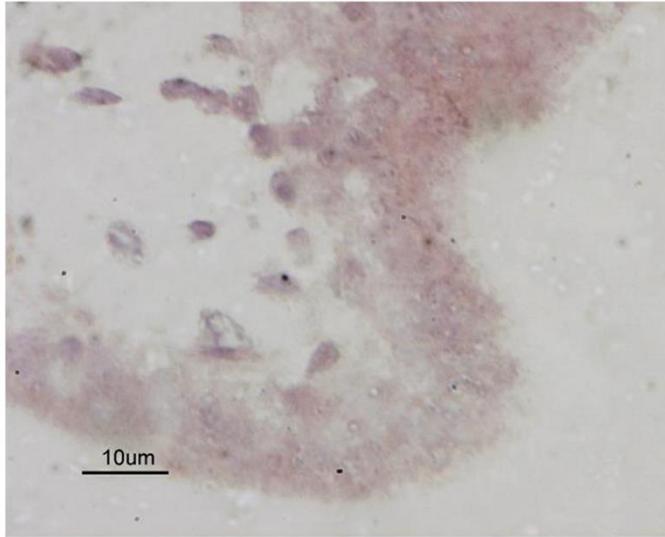

**Supplementary Figure S4. Synteny conservation analyses between IL-17 genes throughout different phyla.** The higher homologies found were presented, which evidences the absence of synteny conservation between the different IL-17 families. Genes were represented with their functional annotation to allow the visualization of putative conservations. Some interesting genes were found repeatedly, as Perlucin, TRIM-2, C1q-related proteins (A), or more frequently Leucine-rich proteins and Ankyrin repeats proteins (B). IL-17 receptor genes also did not show synteny conservation (C).

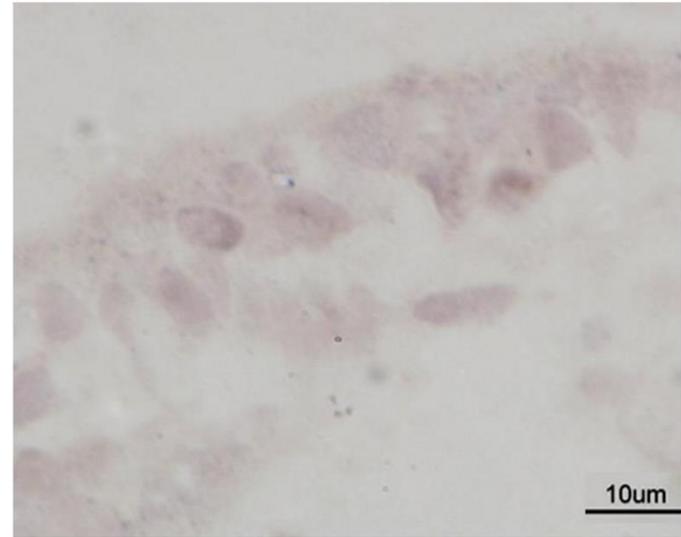

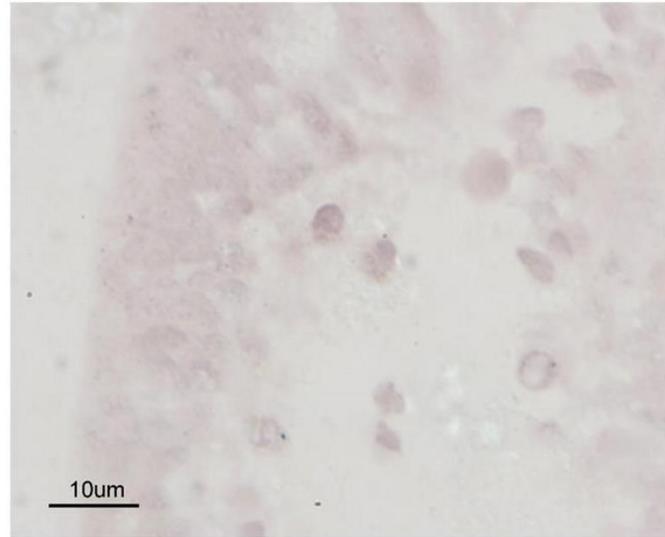

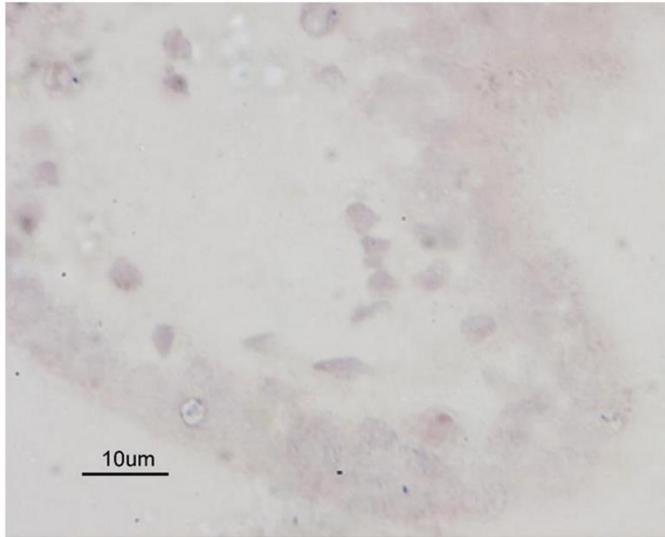

**Supplementary Figure S5. IL-17 homolog genes among the repertoires of chordate vertebrate species did show synteny conservation.** Instead of the absence of it between isoforms from different phyla, vertebrate species maintained synteny conservation as it is represented for IL17-A and IL17-F homologs (A), IL17-D homologs (B) and IL17R-E and IL17R-C homologs (C). Neighbor genes are represented with the official gene symbols in these species. It can be observed as well that in vertebrate species, some IL-17 genes appear together as well, but no tandem repetitions were observed as it happened in the expanded repertoires of marine invertebrates.

**Antisense**

**Sense**

**Supplementary Figure S6. IL17-3 expression at the mRNA level was detected by ISH in histologic preparations of mussel gills using specific antisense RNA probes.** Control samples were hybridized with the sense probes. Replicate sections were used with sense and antisense probes. Alkaline phosphatase detection of hybridized antisense probes in comparison with the absence of colour reaction in the sense probe negative controls reveals expression of IL17-3 mRNA in mussel gills in both epithelial cells and infiltrated hemocytes.
